

What Computers Do

Week 3 - Lecture 3

Simple Algorithms

Edited by: Heshan Du
Autumn 2023

Overview

- Sorting Algorithms
- Search Algorithms
- Type Casting
- Array of Pointers

Example: Module Mark

- There are 3 students in the year. Each of them has taken 2 modules.
- Read their marks one by one, student by student, then print them out module by module.

```
1 #include<stdio.h>
2
3 int main(void){
4
5     const int NUM_STUDENTS = 3;
6     const int NUM_MOD = 2;
7     int marks[NUM_STUDENTS][NUM_MOD];
8
9     int s = 0;
10    int m = 0;
11    for(s = 0; s < NUM_STUDENTS; s++){
12
13        for(m = 0; m < NUM_MOD; m++){
14
15            printf("Student %d, module %d: ", s+1, m+1);
16
17            int mark=0;
18            scanf("%d", &mark);
19            marks[s][m] = mark;
20
21        }
22    }
23
24    printf("\n\nThe marks entered:\n");
25    for(m=0; m< NUM_MOD; m++){
26
27        for(s=0; s< NUM_STUDENTS; s++){
28
29            printf("Student %d, module %d: %d\n", s+1, m+1, marks[s][m]);
30
31        }
32    }
33
34    }
35
36    return 0;
37 }
```

Use nested for loops to solve this problem.

marks

s	m	
	0	1
0	marks[0][0]	marks[0][1]
1	marks[1][0]	marks[1][1]
2	marks[2][0]	marks[2][1]

marks[s][m]

marks[0][0]

marks[0][1]

marks[1][0]

marks[1][1]

marks[2][0]

marks[2][1]

3

```
for (s = 0; s < NUM_STUDENTS; s++)
```

```
{
```

2

```
    for (m = 0; m < NUM_MOD; m++)
```

```
    {
```

```
        ..... marks[s][m].....
```

```
    }
```

```
}
```

marks

s	m	
	0	1
0	marks[0][0]	marks[0][1]
1	marks[1][0]	marks[1][1]
2	marks[2][0]	marks[2][1]

marks[s][m]

marks[0][0]

marks[1][0]

marks[2][0]

marks[0][1]

marks[1][1]

marks[2][1]

2

```
for (m = 0; m < NUM_MOD; m++)
```

```
{
```

3

```
    for (s = 0; s < NUM_STUDENTS; s++)
```

```
    {
```

```
        ..... marks[s][m].....
```

```
    }
```

```
}
```

Example: 2D shapes

- Create a program that holds an 80 x 25 array of characters to show a shape.
- You can change the values in the array as if you were drawing.
- E.g., <http://www.ascii-art.de/ascii/>

Overview

- **Sorting Algorithms**
- Searching Algorithms
- Type Casting
- Array of Pointers

Selection Sort

- Repeatedly find the **minimum element** and swap with the element at the index where it is supposed to be (from the beginning of the array).

<https://www.w3resource.com/php-exercises/searching-and-sorting-algorithm/searching-and-sorting-algorithm-exercise-4.php>

Selection Sort (2)

```
for(i = 0; i < n - 1; i++)  
{
```

Outer Loop

```
    position=i;
```

```
    for(j = i + 1; j < n; j++)
```

Inner Loop

```
    {
```

```
        if(a[position] > a[j])
```

```
            position=j;
```

```
    }
```

```
    if(position != i)
```

```
    {
```

```
        temp=a[i];
```

```
        a[i]=a[position];
```

```
        a[position]=temp;
```

```
    }
```

```
}
```

} swap

```
printf("Sorted Array\n");
```

```
for(i = 0; i < n; i++)
```

```
    printf("%d\n", a[i]);
```

Bubble Sort

Bubble sort or the sinking sort: the smaller values gradually “bubble” their way upward to the top of the array like air bubbles rising in water, while the larger values sink to the bottom of the array.

<https://www.coderarticles.com/bubble-sort-algorithm/>

Bubble Sort (2)

```
int temp = 0;
int i = 0;
int j = 0;

for(i = 0; i < length; i++){
    for(j = 0; j < length-1; j++){
        if(arr[j] > arr[j+1]){
            temp = arr[j];
            arr[j] = arr[j+1];
            arr[j+1] = temp;
        }
    }
}
```

} swap

Overview

- Sorting Algorithms
- **Searching Algorithms**
- Type Casting
- Array of Pointers

Linear Search

A sequential search, every item is checked until the end of the data collection or the item is found.

450
451
452
453
454
455
456
457
458

```
int index = -1;  
for(i = 0; i < count; i++)  
{  
    if(hunt == myInt[i])  
    {  
        index = i;  
        break;  
    }  
}
```

Binary Search

- The linear searching method works well for *small* or *unsorted* arrays.
- However, for large arrays linear searching is *inefficient*.
- *If the array is sorted*, the high-speed binary search technique can be used.
- The binary search algorithm eliminates from consideration *one-half* of the elements in a sorted array after each comparison.

Binary Search (2)

- An array of 1,048,576 (2^{20}) elements takes a maximum of only 20 comparisons to find the search key.
- This is a tremendous increase in performance over the linear search that required comparing the search key to an average of half of the array elements.
- Binary search, focuses on “Divide and Conquer”, requires *sorted array*.

Binary Search

Binary Search: code sample

```
#include <stdio.h>
int main()
{
    int c, first, last, middle, n, search,
    array[100];

    printf("Enter number of elements\n");
    scanf("%d", &n);
    printf("Enter %d integers\n", n);

    for (c = 0; c < n; c++)
        scanf("%d", &array[c]);

    printf("Enter value to find\n");
    scanf("%d", &search);

    first = 0;
    last = n - 1;
    middle = (first+last)/2;
```

```
    while (first <= last) {
        if (array[middle] < search)
            first = middle + 1;
        else if (array[middle] == search) {
            printf("%d found at location %d.\n", search,
middle+1);
            break;
        }
        else
            last = middle - 1;

        middle = (first + last)/2;
    }
    if (first > last)
        printf("Not found! %d isn't present in the list.\n",
search);

    return 0;
}
```

```
#include <stdio.h>
int main()
{
    int c, first, last, middle, n, search, array[100];

    printf("Enter number of elements\n");
    scanf("%d", &n);
    printf("Enter %d integers\n", n);

    for (c = 0; c < n; c++)
        scanf("%d", &array[c]);

    printf("Enter value to find\n");
    scanf("%d", &search);

    first = 0;
    last = n - 1;
    middle = (first+last)/2;
```

```
while (first <= last) {  
    if (array[middle] < search)  
        first = middle + 1;  
    else if (array[middle] == search) {  
        printf("%d found at location %d.\n", search, middle+1);  
        break;  
    }  
    else  
        last = middle - 1;  
    middle = (first + last)/2;  
}  
  
if (first > last)  
    printf("Not found! %d isn't present in the list.\n", search);  
  
return 0;  
}
```

Binary Search: new solution, what do you think?

```
#include <stdio.h>
int binarySearch(int a[], int s, int e, int f);

int main()
{
    int c, first, last, n, search, array[100], index;

    printf("Enter number of elements\n");
    scanf("%d", &n);

    printf("Enter %d integers\n", n);

    for (c = 0; c < n; c++)
        scanf("%d", &array[c]);

    printf("Enter value to find\n");
    scanf("%d", &search);

    first = 0;
    last = n - 1;

    index = binarySearch(array, first, last, search);
```

```
if (index == -1)
    printf("Not found! %d isn't present in the list.\n", search);
else
    printf("%d is present at location %d.\n", search, index +
1);

    return 0;
}

int binarySearch(int a[], int s, int e, int f) {
    int m;

    if (s > e) // Not found
        return -1;

    m = (s + e)/2;

    if (a[m] == f) // element found
        return m;
    else if (f > a[m])
        return binarySearch(a, m+1, e, f);
    else
        return binarySearch(a, s, m-1, f);
}
```

Overview

- Sorting Algorithms
- Searching Algorithms
- **Type Casting**
- Array of Pointers

Type Casting

- Convert the type of an expression to another type
- (data_type) expression
- float a, b, c = 2.34;
b = (int)(c+4.6)

b is 6

Explicit Type Conversions

- Implicit type conversion

```
float f;
```

```
int i;
```

```
i = f;
```

- Explicit type conversion

```
float f;
```

```
int i;
```

```
i = (int) f;
```

Same result, but for explicit type conversion the reader knows for sure that it was intentional!!

Initialisation

Example: variable initialized where declared

```
int max = 0;
/* use of max is within a page of where it is declared */
for (i=0; i<n; i++)
    if (vec[i] > max)
        max = vec[i];
```

Example: variable initialized where used

Use an assignment statement just before the for loop:

```
int max;
...
/* several pages between declaration and use */
...
max = 0;
for (i=0 ; i<n ; i++)
    if (vec[i] > max)
        max = vec[i];
```

Overview

- Sorting Algorithms
- Search Algorithms
- Type Casting
- **Array of Pointers**

2D Array and Array of Pointers

- Array of pointers can be helpful in handling character array with varying length.

```
char *name[3] = {  
    "Adam",  
    "chris",  
    "Deniel"  
};  
//Now lets see same array without using pointer  
char name[3][20] = {  
    "Adam",  
    "chris",  
    "Deniel"  
};
```

Using Pointer

char* name[3]

Only 3 locations for pointers, which will point to the first character of their respective strings.

Without Pointer

A	d	a	m			
c	h	r	i	s		
D	e	n	i	e	l	

char name[3][20]

extends till 20 memory locations
